ABSTRACT

The present communication deals with some kaolin horizons at Wadi El-Esseila, West Central Sinai, in an attempt to deduce their origin and evaluate their economic potentialities. 147 representative kaolin samples were chemically analysed for their major element oxides while 19 were selected, in addition to 11 samples from the host Nubia Formation and subjected to trace-element analysis. The mineralogy of the deposit has been identified through D.T.A. and X-ray diffraction analyses. The heavy minerals were separated and their types as well as characteristics were interpreted.

Based on these studies, the kaolin deposits are assigned a detrital sedimentary fluvio-marine environment & were derived principally from the southern basement rocks. However, more than one province have contributed to their formation. Not all the kaolin horizons are economically of the same grade.

INTRODUCTION

Wadi El-Esseila area lies at West Central Sinai, near the eastern side of Gulf of Suez; about 25 Km to the northeast of Abou-Zneima (Fig. 1). The Wadi trends NNE-SSW sepaDelta J. Sci. (11) (3) 1987 Origin and economic aspects of some kaolin deposits.....

rating Gebel El-Esseila to the east and Gebel Abu-Ediemat to the west.

The kaolin deposits are represented by four and in some places five horizons locally termed Horizons I-IV, where Horizon (I) is given to the lowermost exposed level in the Wadi. Each horizon is typified by flat & disconnected lenses that range in thickness from 0.5 to 4 meters. Worthmentioning that Horizon II as well as Horizon III represent the thickest ones and are laterally extended for longer distances. For this, stress has been given to these two horizons being subject of economic scale.

The five kaolin horizons are intraformationally layered with the Nubia Formation which is given a questionable lower Cretaceous age? on basis of its relative stratigraphic position. Figure 2 shows a composite columnar section for the study area. The kaolin horizons are separated from each other by interval of about 2-8 mts, each displaying gradation into the sandstone through a thin kaolinitic sandstone.

Chemistry of the kaolin horizons:

1- Major oxides:

147 samples (114 composite & 33 spot) representing kaolin horizons II & III were chemically analysed for

Delta J. Sci. (11) (3) 1987 M. A. El-Askary <u>et al</u>.

their major oxides SiO_2 , $\mathrm{Al}_2\mathrm{O}_3$ + TiO_2 , $\mathrm{Fe}_2\mathrm{O}_3$, CaO , MgO and $\mathrm{L.O.I.}$ Both horizons display wall to wall variation either in grade or in colour. Each horizon was compositely sampled but separately analysed. The thickness at sampling locations was measured and average oxides content for the whole lens is calculated.

1.1. silica:

The silica content showed wide variation (tables 1-4), spot sample analysis revealed that silica content increases toward contact with sandstone. As silica is an inverse function of kaolin grade, the central parts of the lens render higher grade.

1.2. Alumina + Titania:

The close association between ${\rm Al}_2{\rm O}_3$ and ${\rm TiO}_2$ with kaolin grade has been proved by many workers: [1,2,3] among others. It is a fact that alumina content is directly proportional to the kaolin grade and inversely to the silica content (Fig. 3).

Variation in the two oxides $(Al_2O_3 \& TiO_2)$ together as well as variation of each separately in 18 representative (11 composite + 7 spot) samples is given in tables 1-4.

Normal values of kaolin grade are obtained, yet high

Delta J. Sci. (11) (3) 1987 Origin and economic aspects of some kaolin deposits

titania could be observed in some samples. This relatively high titania in such deposits may be attributed to:

- a- The presence of some Ti-bearing heavy minerals as rutile, ilmenite, and leucoxene, Such factor is verified by heavy-mineral studies as will be shown later.
- b- Minor amounts of Ti may replace Al in the octahedral position or Si in the tetrahedral position.
- c- Some amorphous or hydrated TiO₂ may be deposited together with tiny kaolinite flakes [4]

1.3. Iron oxide:

Colour shades of kaolin usually reflect iron content among other elements. Yellowish brown to reddish brown or even purple colour is usually noticed near sandstone wall rocks. It is thought that a large part of this iron oxide is due to precipitation from colloids that came from the highly porous & permeable sandstone to the kaolin causing its staining. The content of iron oxides in different coloured kaolin samples is listed in tables 1-4.

1.4. Calcium oxide:

Calcium oxide is present in minor amounts. Tables 1-4 show its range in the different samples. Worthmentioning that CaO is considered to be one of the harmful oxides in kaolin refractory.

Delta J. Sci. (11) (3) 1987 M. A. El-Askary <u>et al</u>.

1.5. Magnesium oxide:

MgO as well follows CaO in its presence as very subordinate. It never exceeds 0.44% in average.

Chemical data presentation:

For economic purpose, chemical data is presented by preparing isochemical maps for the different analysed element-oxides in each lens. Also average values in both lenses have been calculated. In addition, isopach maps were constructed. Selection of Gebel Abu Ediemat only for such presentation was essentially due to the larger number of representative samples it yielded.

From isopach & isochemical maps, the following observations could be given:

- a- The thickness of both horizone (II & III) was found to be increasing via NW direction (Fig. 4).
- b- The average SiO₂ content showed increase towards SE. This is true for both horizons as a whole, yet the remarkable variation in SiO₂ content revealed in horizon II rendered stating of a general trend is rather risky (fig. 5).
- c- Average (${\rm Al}_2{\rm O}_3$ + ${\rm TiO}_2$) showed observable increase via NW direction (Fig. 6), being directly proportional with thickness but inversely with average ${\rm SiO}_2$.

Delta J. Sci. (11) (3) 1987 Origin and economic aspects of some kaolin deposits....

d- Iron oxide, although varies in the one horizon, yet a general slight increase could be deduced towards NE and SE directions (Fig. 7).

2- trace-element analysis:

Trace-element studies on clay deposits in general are believed to have something to do with the depositional environment but nothing regarding economicity. Boron, Vanadium, Cobalt, Nickel and Copper are among the useful trace elements in that connection. Nineteen kaolin and 11 sandstone samples (from the host Nubia Formation) were optically arced by means of Q-24 medium quartz emission sepectrograph and analytical results for the mentioned trace elements are listed in tables 5 & 6.

Boron as a paleosalinity indicator and hence differentiating between marine and lacustrine environments has been stressed upon by Goldschmidt and Peter [5]. This has been confirmed by Harder [6] and Levinson & Ludwick [7] when they found that sediments near river mouths are characterized by lower boron content than those deposited in open sea conditions, Also, Degens et al. [8] concluded that boron as well as rubidium are higher in marine shales opposite to gallium. Keith & Degens [9] reconfirmed the previous conclusions adding the elements Li, S, Mn, Ni, F, and Sr to be higher in marine shales while Ga, Cr, and V are higher in fresh water shales. Harder [10] concluded that boron content in

Delta J. Sci. (11) (3) 1987 M. A. El-Askary et al.

clays is dependant on: depositional conditions, grain size and type of dominating clay mineral. In addition, Parks and White [1] reported the inability of the H-saturated form of kaplinite and bentonite for boron fixation. In other context, Porrenga [12] attributed increase of boron absorption by clays to temperature increase.

It is worthy to note that boron content in Wadi El-Esseila clays is considered among the low values attained by clays. This leads to conclude that such clay deposits are of freshwater media, not high in temperature and were formed in H-saturated form.

On the other hand, Porrenga [12] emphasized that Ni, Cr and Sr are slightly higher in marine clays than fresh water clays. Wadi El-Esseila clays show relatively high Mn & Sr whereas Ni & Cr Values are matching those of marine clays.

Such discrepancies in trace element contents of Wadi El-Esseila clays as regards to certain environmental conditions make hypothesis of a fluviomarine environment is possible. More support is evidenced on applying V-Co+Ni-Cu diagram constructed by Angino and Andrews [13] for differentiating sedimentation conditions.

Delta J.Sci. (11)(3)1987 Origin and economic aspects of some kaolin deposits....

The plots of Wadi El-Esseila clays lie mostly in or very near from shallow-water sediments field.(Fig. 3)

Mineralogy of kaolin horizons:

Twenty five samples were derivatographically analysed where as 21 samples were investigated using X-ray diffraction analysis to identify the mineralogy of the chemically analysed kaolin horizons.

Differential thermal analysis results showed that kaolinite is the main constituent (Figs. 9 & 10). In addition, kaolinite mineral displays wide range in crystallinity from weak to rather well crystalline. The well crystallinity nature is rather dominant among samples representing Horizon II. The high percentage of kaolinite affects the α - β inversion peak of quartz rendering it masked even in those samples chemically proved to be of high quartz-content.

Worthmentioning that X-ray diffraction interpretation matched well the results of derivatographic analysis. The degree of peaks sharpness indicates the well crystalline nature of kaolinite displayed by Horizon II samples only (Fig. 11). Moreover, results hitherto given from chemical analysis concerning the inverse relation between quartz content and kaolinite grade is reconfirmed.

Delta J.Sci;(11)(3)1987 M. A. El-Askary et al.

Heavy minerals:

Heavy minerals study is affectionally used in interpreting type of source rocks, environmental conditions and to some extent diagenesis. Twenty sandstone samples as well as 12 kaolins were subjected to heavy mineral separation techniques and microscopically examined. Results are summarized in the following:

- 1- Opaques form high percent relative to others in heavy fraction.
- 2- Zircon, tourmaline, rutile, staurolite and biotite represent the non-opaque heavy minerals, displaying different forms. sizes and colours.
- 3- Zircon, tourmaline and rutile -usually considered as ultrastable-dominate the other non opaques.
- 4- The index figure for sandstone samples is little bit higher than that of kaolin ones but grading to be matched near contacts.

From these results one reaches the following conclusions:

- 1- The essential heavy mineral assemblages recorded from the Nubia Sandstone samples and their intercalated kaolin are more or less comparable to those recorded by several authors in the Nubia Sandstone at different localities [2,3, 14-18].
- 2- The variation in form, size and colour of the ultrastable

Delta J. Sci. (11) (3) 1987

Origin and economic aspects of some kaolin deposits ...

- nonopaques may lead to the assumption that more than one provenance acted as a source.
- 3- The high frequency of the ultrastable non-opaque minerals has been explained in two ways; one considers that mineralogy of the Egyptian sediments appears to be governed by both depositional environment and provenance [16]. The other relates it to post-depositional changes with special emphasis on the effect of intrastratal solutions [17]. However, Hubert [19] gave little attention to the effect of intrastratal solutions in determining the heavy minerals assemblage stating that it is a local phenomenon. Meanwhile, two points must be mentioned to unravel which factors were controlling in obtaining such high percentage of the ultrastable non-opaque minerals. These are the following:
 - a- Matching or nearly so of the index figure of both hard, permeable Nubia sanstone and that of soft, impermeable kaolin is in favour of the first explanation.
 - b- The presence of etched together with unetched mineral grains in the same sample opposes the effect of intrastratal solutions as an explanation,
- 4- Hubert [19] used ZTR index (% of combined ziron, tourmaline and rutile) to define sandstone types. He mentioned that such index is high (> 90%) in tectonic sandstone He added that in such sandstone types, a lot of zircon, tourmaline and rutile grains, different in colour,

Deita J. Sci. (11) (3) 1987 M. A. El-Askary <u>et al</u>.

inclusions and form, are usually characteristic. Worthy to mention that ZTR index in Wadi El-Esseila Nubia sandstones exceeds 90%.

ORIGIN OF WADI EL-ESSEILA HAOLIN DEPOSITS

Data and observation provided by mineralogical studies lead speculation for history of formation of Wadi El-Esseila kaolin as follows:

- -Weathering of the basement rocks (most probably of acidic composition as indicated by the low Fe content) which occur to the southeast of the study area. The weathering products were mainly formed of feldspars and quartz grains.
- -Feldspars were changed into kaolinite, by chemical weathering under acidic conditions with high rainfall and good drainage.
- -These products were transported by numerous northwards streams and were deposited in geomorphologically shaped depressed areas, followed by Nubia Sandstone deposition.
- It seams plausible that this scenario has been repeated more than once to form the different horizons in the area.

The presence of the sedimentary features that characterize sediments formed by deltaic processes (such as the lateral and vertical variations in the amount of kaolinite, sand and iron staining within short distances), the presence

Delta J. Sci. (11) (3) 1987

Origin and economic aspects of some kaolin deposits.....

of the deposit in the form of irregular isolated lenses and the absence of minerals of hydrothermal origin such as dickite and nacrite in addition to the absence of criteria supporting other modes of formation indicate sedimentary environments for Wadi El-Esseila kaolin deposits.

ECONOMIC ASPECTS OF WADI EL-ESSEILA KAOLINITES

From the chemical point of view, the kaolin of the study area is satisfactory for the manufacture of refractories, this is mainly due to its relatively high alumina content which is accompanied by minor amounts of both iron, calcium and magnesium oxides.

SUMMARY AND CONCLUSION

Kaolin deposits of Wadi El-Esseila are found in the form of separated disconnected lenses within an unfossiliferous Nubia Sandstone deposit which is given a questionable lower Cretaceous age. 147 kaolin samples were chemically analysed in order to evaluate the potentialities of the kaolin deposits for manufacture. The thicknesses of the most economic kaolin lenses (the second and the third ones) were traced laterally and the average contents of the oxides SiO_2 , $(\mathrm{Al}_2\mathrm{O}_3 + \mathrm{TiO}_2)$ and $\mathrm{Fe}_2\mathrm{O}_3$ were calculated. Isochemical maps were drawn and correlated with their thickness maps.

The trace element data of 19 kaolin samples and 11

Delta J. Sci. (11) (3) 1987 M. A. El-Askary <u>et al</u>.

sandstone ones showed that both of the kaolin and sandstone were deposited under a shallow water environment most probably a fluvio-marine one. In addition, 25 kaolin samples were derivatographically analysed and 21 samples were investigated by X-ray diffraction analysis. Results indicate that kaolinite is the main constituent, associated with some quartz and no other clay minerals are recorded.

Zircon, tourmaline, rutile, staurolite and biotite represent the non opaque heavy minerals in both the sandstone and interformational kaolin horizons. The ultrastable non opaque heavy minerals (zircon, tourmaline and rutile) are -by far- the most frequent among the other non opaques. They display differences in form, size and colour which may lead to assume that more than one provenance was contributing for the same mineral species. The basement rocks lying to the southeast of the investigated area seems to be playing the principal role, probably in addition to a reworked sedimentary provenance.

ACKNOWLEDGMENTS:

The authors are grateful for the great facilities offered by the Egyptian Company for Refractories, major element analyses were performed at the laboratories of the company. We would like to express our gratitude to geologists of the company at the Sinai profit for their great help during field work.

نشاة والاهميه الاقتصادية لرواسب الكاولين بمنطقة وادى العسيلة والاهميه الاقتصادية لرواسب الكاولين بمنطقة وادى العسيلة

د محمد ابو اليزيد العسكري د جلال عويس , د سمير محمود الشادلي محمد ناصر شعبان كلية العلوم _ جامعة الاسكندرية _ قسم الجيولوجيا

يتناول هذا البحث دراسة لبعض طبقات الكاولين بمنطقة وادي العسيله في وسط غرب سينا، في محاولة لتحديد اصل وطريقة تكوين هذا الخام ، بالاضافة الى عدير اهميتة الاقتصادية ، ولقد تم تحليل كيميائي لعدد ١٤٧ عينة لخام الكاولين بالمنطقة بالنسبة للعناصر الرئيسية كما تم اختيار ١٩ عينة منها لتميين العناصر الشحيحة بالاضافة الى

الرئيسية كما تم اختيار ١٩ عينة منها لتهيين العناصر الشحيحة بالاصافة الى المعدني من صخور الحجر الرملي الحاوى لطبقات الكاولين ١٠ اما عن التركيب المعدني لرواسب الكاولين فقد اوضحت منحنيات التحليل الحرارى النفاضلي والوذني لعدد ٢٥ عينة كاولين وكذا نظم التشتت الاشعاعي الناتجة من معاملة ٢١ عينة كاولين بالاشعة السينية ان معدن الكاولينيت هو المكون الاساسي لرواسب الكاولين ولا توجد معادن طين اخرى ٠ تضمن البحث كذلك دراسة للمعادن النقيلة لبعض عينات الحجر الرملي والكاولين لتحديد انواع وخصائعي هذه المعادن ٠

ولقد اثبتت هذه التحاليل ان خام الكاولين قد ترسب تحت بيئة مياه ضحلة محتمل ان تكون بيئة بحرية _ نهرية وان طبقات هذا الخام قد تكونت نتيجة التحلل الكيميائي للمعادن الالومينوسليكاتية (فلسبادات اساسا) بواسطة عوامل التجوية المناسبة في الصخور الحالمة لها (صخور حمضية كما يستدل على ذلك من القيم المنخفضة عبوما لاكسيد الحديديك) وكونت راسبا متبقيا من الكاولين في الاجزاء العليا لهذه الصخور , ثم نقل الكاولين بعد ذلك بعوامل النقل الى حغر طبقية الشكل تكونت جيومورفولوجيا في سطح الحجر الرملي النوبي ليترسب فيها عثم تاتي مرحلة لاحقة ليترسب الحجر الرملي النبي فوق عدسات الكاولين , وبتكرار هذه العملية تم ترسيب الطبقات المختلفة لخام الكولين في فترات زمنية متتابعة .

ومن الجدير بالذكر ان العدستان الثانية والثالثة (من اسغل) لخام الكاولين تتميزان بقيمة اقتصادية اكبر من باقى العدسات حيث انهما اعلى جوده وتمتدان لمسافة جانبية اطول وتتمتعان بسمك رأسى كبير.
